## ECE 220: Computer Systems & Programming

Review: Computers are Dumb

## Lend Me Your Brains for a Minute?

I had a busy break.

**I need to ask your help.**

**Can you help me sort these numbers?**

“41,962” “41321” “9874”  
biggest middle smallest

## Are You Sure About Your Answers?

Hmm. Are you sure?

I just ask because, well ...

I asked my computer, too.

And **it gave different answers:**

	“41,962”	“41321”	“9874”
humans	biggest	middle	smallest
computers	smallest	middle	biggest

## A Side-by-Side Comparison of the Numbers

Let's compare them side by side.

41,962

41321

9874

**What's bigger, “4” or “9?”**

Oh, so **“9874” is the biggest!**

Please be more careful when you help me!

## A Side-by-Side Comparison of the Numbers

What's the next largest?

41,962  
41321  
9874

Compare these two.

"4" is equal to "4."

"1" is equal to "1."

What's bigger, "," or "3"?

Ah, so "41321" is the middle value. Good.

Comma (x2C)  
is smaller than  
'3' (x33).

## So the Computer is Right?

It seems that the computer is right.

At least, for some definition of "right."

This type of answer is what you get if you **sort strings in ASCII order** (instead of numerical order).

	"41,962"	"41321"	"9874"
humans	biggest	middle	smallest
computers	smallest	middle	biggest

## Remember: Computers are Dumb

Think it's just a silly example?

Take a look at the index of Patt and Patel.

Should "EXTERNAL" come before "Equality"?

"ASCII" before "Address"?

Computers do exactly what they are told.

## Another Example: Adding Strings

Here's a **software representation** for a **string of text** (the string is "19").

The **address** of the first **ASCII** character in memory, **x4012**, is **used to represent the string**.

x4012	x0031	'1'
x4013	x0039	'9'
x4014	x0000	NUL

To "read" the string,

- look at consecutive memory locations
- until we find a **0** (an **ASCII NUL** character),
- which indicates the end of the string.

## Can We Add Two Strings?

Here's another string.

**What is it? "23"**

Say that the **LC-3** executes:

**R1** ← **x4012**

**R2** ← **x7196**

**R3** ← **R1 + R2**

**What is R3? xB1A8**

**What is stored at xB1A8? Bits!**

<b>x4012</b>	<b>x0031</b>	<b>'1'</b>
<b>x4013</b>	<b>x0039</b>	<b>'9'</b>
<b>x4014</b>	<b>x0000</b>	<b>NUL</b>
<b>x7196</b>	<b>x0032</b>	<b>'2'</b>
<b>x7197</b>	<b>x0033</b>	<b>'3'</b>
<b>x7198</b>	<b>x0000</b>	<b>NUL</b>

## You Understand Why Adding Addresses Doesn't "Work"

Obviously, if we want to add two strings that represent numbers, we need to do more work.

People who have never seen representations using bits often cannot understand such failures.

Almost every bug you write will seem this dumb when you find it.

I've seen bugs take months.

People don't like to talk about them afterward.
